## ECE 341-Test \#3: Name

Markov Chains and Data Analysis

1) Markov Chains: Assume five players are tossing a ball around.

- Each second the player with the ball tosses it.
- The probability that the player tosss the ball to someone else is shown below.
- At $\mathrm{k}=0$, player A has the ball.
a) Express the probability that a player has the ball after k tosses as:

$$
X(k+1)=M X(k)
$$

where $\mathrm{X}(\mathrm{k})$ is the probability that player $\{\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}\}$ has the ball at toss \#k.

b) Determine the probability that A has the ball after 10 tosses.

- or explain how you would find this if you don't have access to Matlab

2) t-Test (One data set). A 4 -sided die may or may not be loaded. If it's a fair die, the mean of the die rolls should be 2.5 .

- Use a t-test to determine the probability that the mean of the die is in the range of $(2.4,2.6)$
- (i.e. is this a fair die?)
- note: This is population question

| 1's | 2's | 3's | 4's | mean | st dev | \# rolls |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 29 | 20 | 31 | 20 | 2.4200 | 1.1117 | 100 |
| $p(2.4<\mu<2.6)=?$ |  |  |  |  |  |  |

3) $t$-Test (Two data sets): Two four-sided dice are rolled $N$ times. They might be fair dice, they might both be loaded dice.

Determine the probability that the mean of die A is within 0.1 of the mean of B

- i.e. $-0.1<\mu_{a}-\mu_{b}<0.1$
- note: this is a population question

|  | 1 's | 2's | 3 's | 4's | mean | st dev | \# rolls |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| A | 29 | 20 | 31 | 20 | 2.4200 | 1.1117 | 100 |
| B | 14 | 23 | 22 | 21 | 2.6250 | 1.0599 | 80 |
| $p\left(-0.1<\mu_{a}-\mu_{b}<+0.1\right)=?$ |  |  |  |  |  |  |  |

4) Chi-Squared Test: A 4-sided die is rolled 100 times. Determine if this is a fair die using a chi-squared test

| 1's | 2's | 3's | 4's | mean | st dev | \# rolls |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 29 | 20 | 31 | 20 | 2.4200 | 1.1117 | 100 |

5) ANOVA (Three data sets): Three 4-sided dice are rolled. They may or may not be loaded.

Use an ANOVA test to determine if the three dice have the same mean

|  | 1's | 2's | 3's | 4's | mean | st dev | \# rolls |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| A | 29 | 20 | 31 | 20 | 2.4200 | 1.1117 | 100 |
| B | 14 | 23 | 22 | 21 | 2.6250 | 1.0599 | 80 |
| C | 20 | 12 | 14 | 14 | 2.3667 | 1.1784 | 60 |
